Designing, Visualizing and Understanding Deep Neural Networks

Lecture 6: Convolutional Networks II

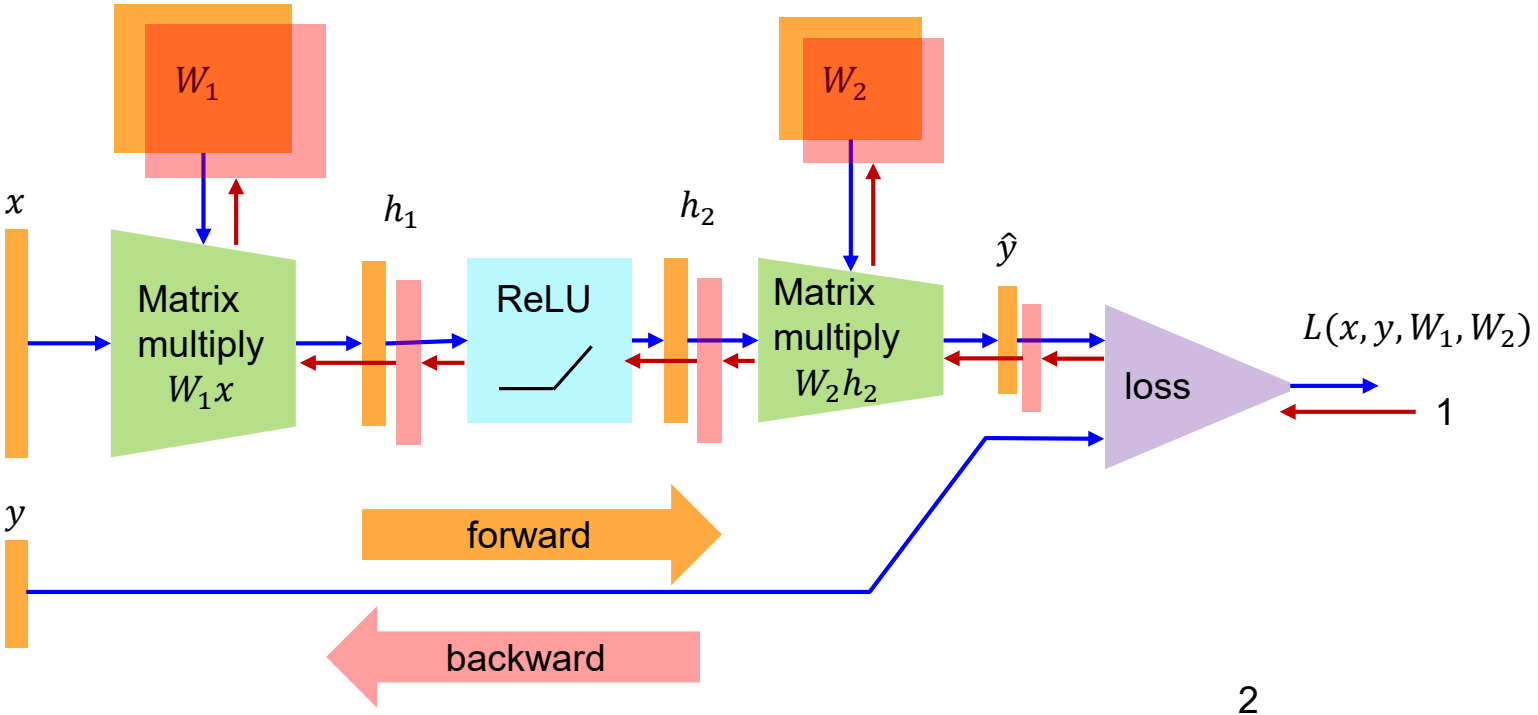
CS 182/282A Spring 2020
John Canny

Slides originated from Efros, Karpathy, Ransato, Seitz, and Palmer

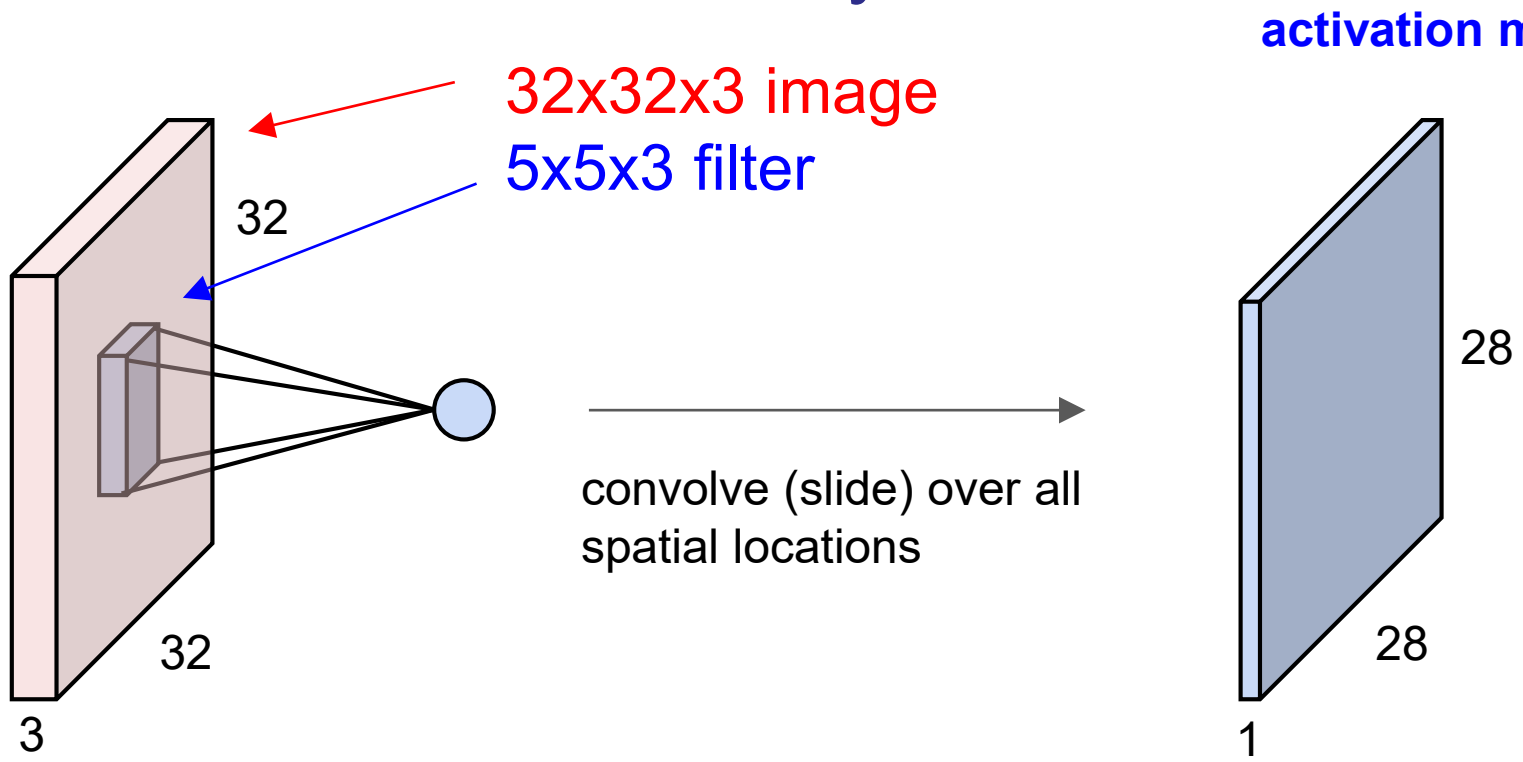
Last Time: Backpropagation

Backprop Efficiency: matrix-vector multiply only and common subexpressions.

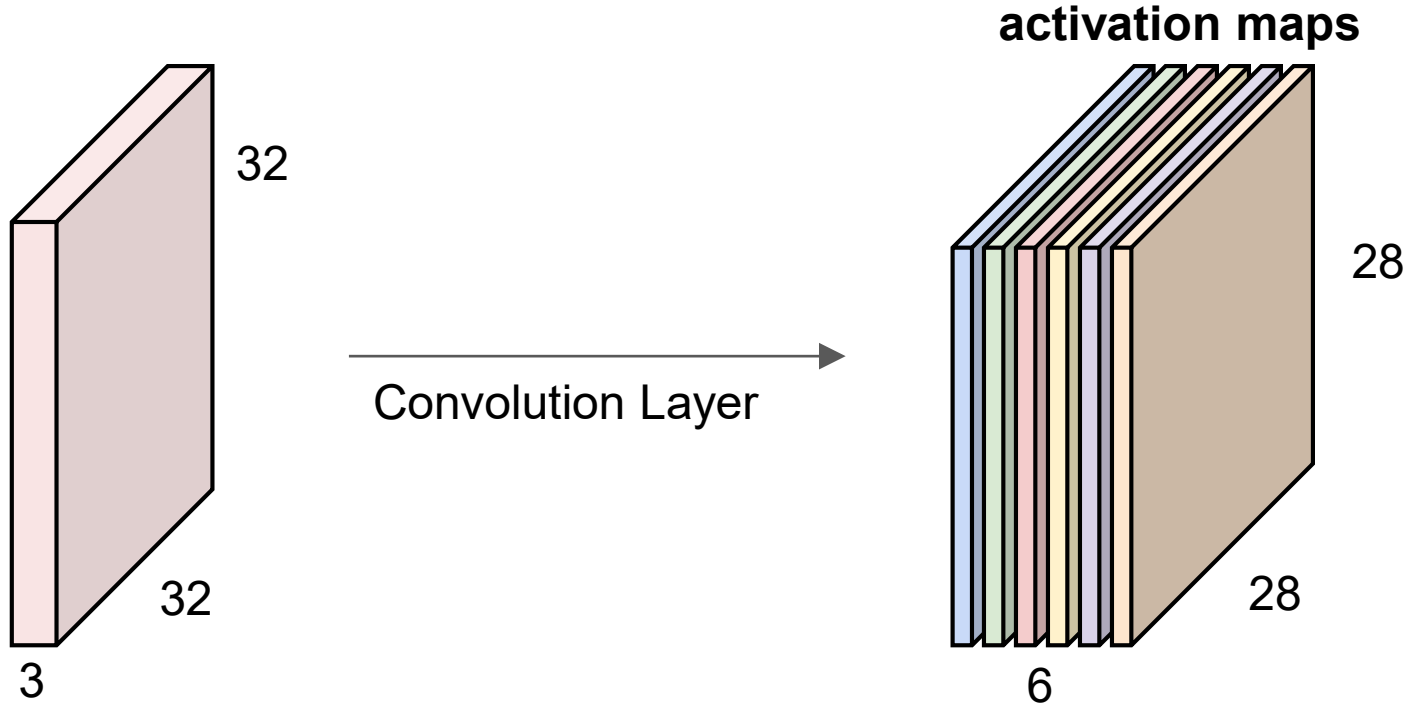
Example: a real neural network (Tensorflow style):



Last Time: Convolution Layers



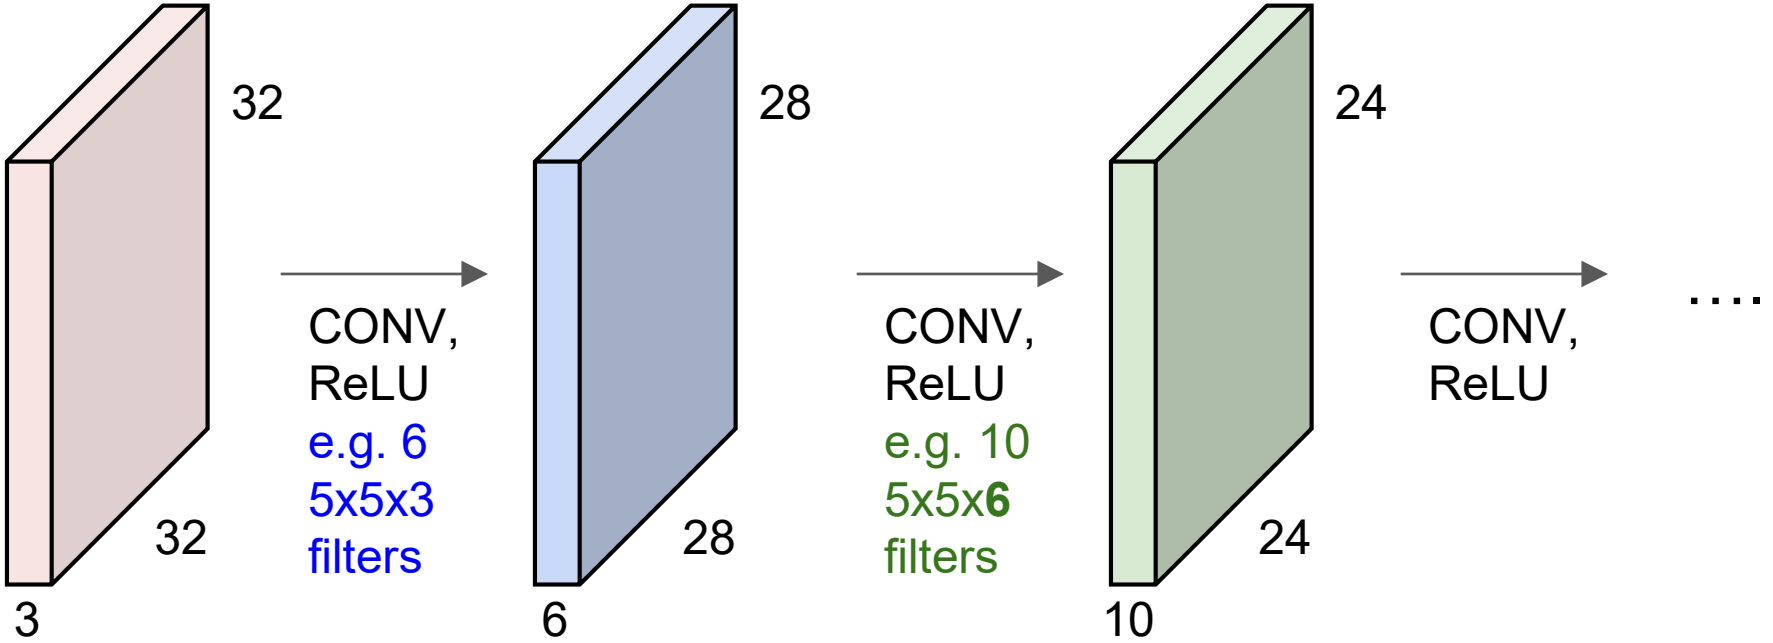
Last Time: Convolution Layers



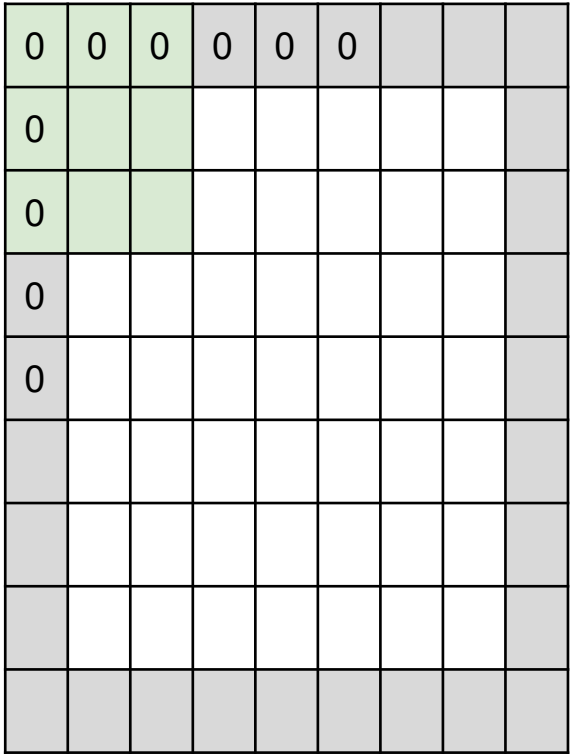
We stack these up to get a “new image” of size 28x28x6!

Diminishing Returns…

A 32x32 input convolved repeatedly with 5x5 filters shrinks volumes spatially! (32 -> 28 -> 24 ...). Nothing left after 8 layers…



In practice: Common to zero pad the border

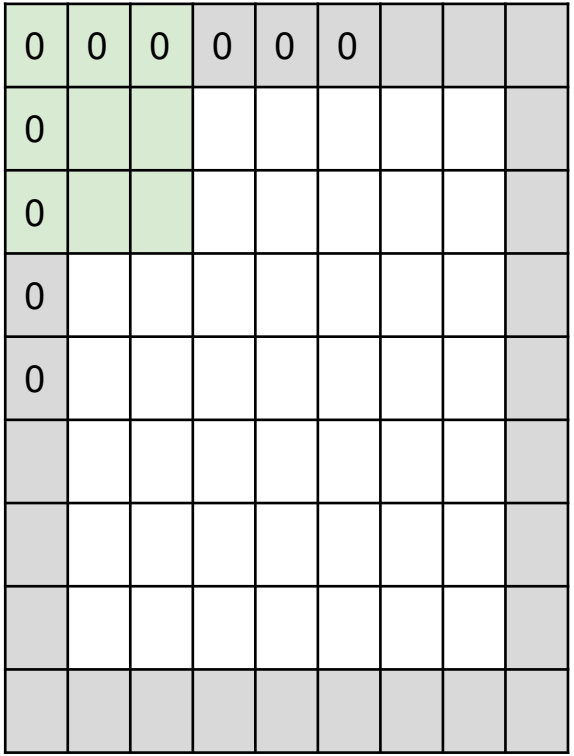


Aside: remove image mean first!

e.g. input 7x7
3x3 filter, applied with **stride 1**
pad with 1 pixel border => what is the output?

(recall:)
(N - F) / stride + 1

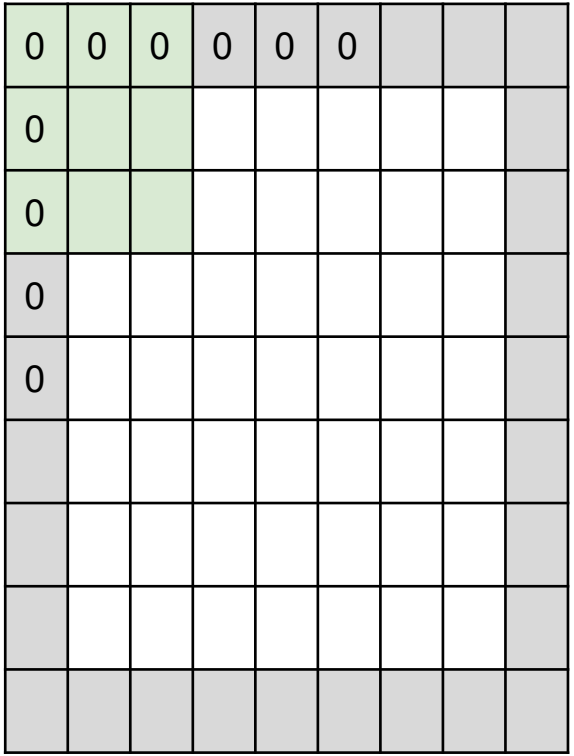
In practice: Common to zero pad the border



e.g. input 7x7
3x3 filter, applied with **stride 1**
pad with 1 pixel border => what is the output?

7x7 output!

In practice: Common to zero pad the border



e.g. input 7x7
3x3 filter, applied with **stride 1**
pad with 1 pixel border => what is the output?

7x7 output!
in general, common to see CONV layers with stride 1, filters of size FxF, and zero-padding with (F-1)/2. (will preserve size spatially)
e.g. F = 3 => zero pad with 1
F = 5 => zero pad with 2
F = 7 => zero pad with 3

When the Filter doesn't fit:

Our new formula with padding on both sides is:

$$D_{out} = (N + 2P - F)/\text{stride} + 1$$

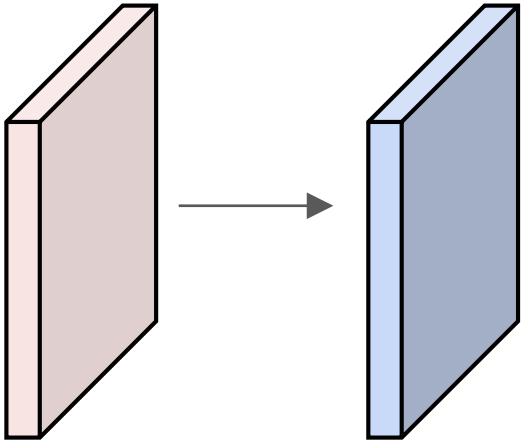
(the effective image size is now $N + 2P$).

So the number of strided steps we can take may not be an integer.

But we can still take the next-smallest integer number of steps.
In practice almost all deep learning toolkits simply round down to the nearest integer in this case (disregard the cs231n notes on this point). i.e.

$$D_{out} = \lfloor (N + 2P - F)/\text{stride} \rfloor + 1$$

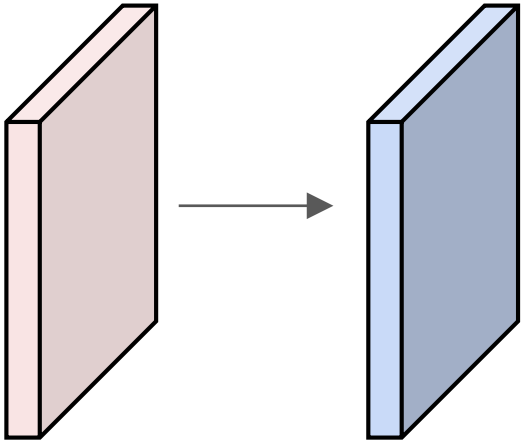
Examples:



Input volume: **32x32x3**
10 5x5 filters with stride 1, pad 2

Output volume size: ?

Examples:



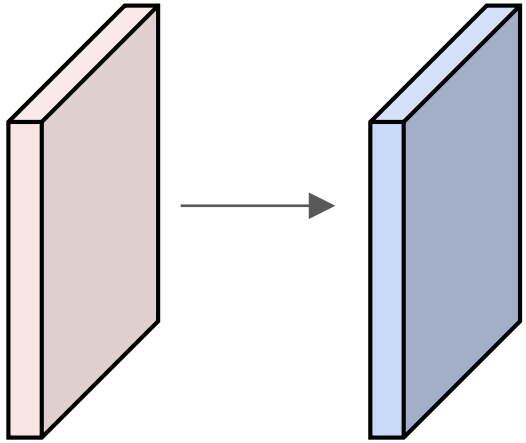
Input volume: **32x32x3**
10 5x5 filters with stride 1, pad 2

Output volume size:
(32+2*2-5)/1+1 = 32 spatially, so
32x32x10

Examples:

Input volume: **32x32x3**
10 5x5 filters with stride 1, pad 2

Number of **parameters** in this layer?



A. 32x32x10 = 10240

B. 32x32x3x10 = 30720

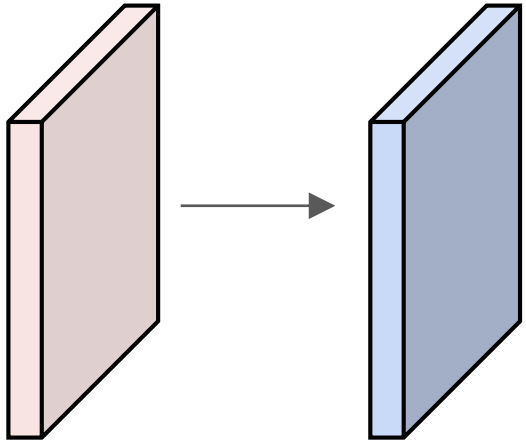
C. (5x5x3+1)x10 = 760

D. (5x5+1)x10 = 260

Oops!

Input volume: **32x32x3**
10 5x5 filters with stride 1, pad 2

Number of **parameters** in this layer?



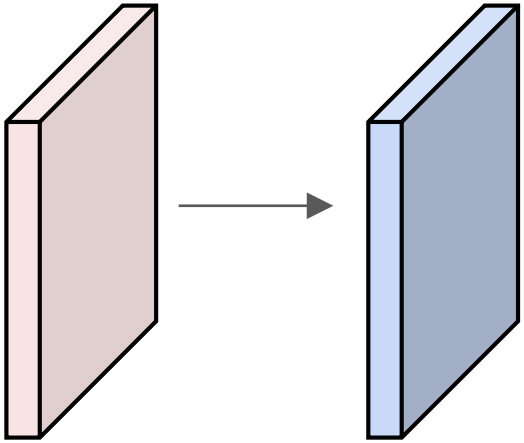
A. 32x32x10 = 10240

This is the output volume

Try Again

Continue

Oops!



Input volume: **32x32x3**
10 5x5 filters with stride 1, pad 2

Number of **parameters** in this layer?

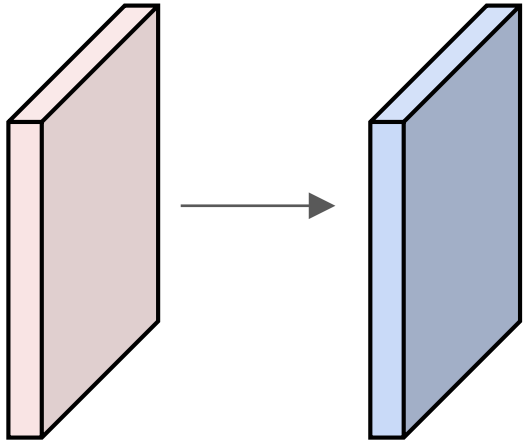
B. 32x32x3x10 = 30720

This is the output volume x 3.

Try Again

Continue

Yes!



Input volume: **32x32x3**
10 5x5 filters with stride 1, pad 2

Number of **parameters** in this layer?

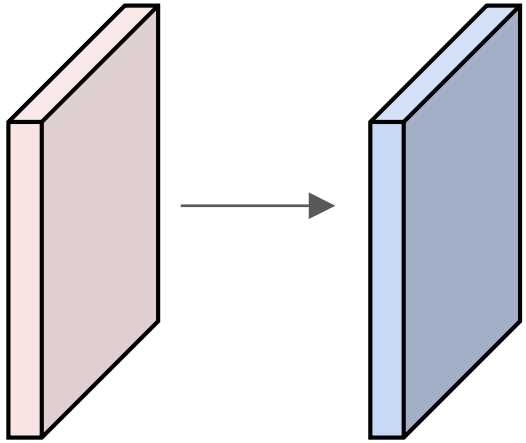
C. (5x5x3+1)x10 = 760

Each filter has 5x5x3 parameters for the filter, +1 for bias, and there are 10 filters.

Try Again

Continue

Oops!



Input volume: **32x32x3**
10 5x5 filters with stride 1, pad 2

Number of **parameters** in this layer?

B. (5x5+1)x10 = 260

This ignores the input depth of the filters (3).

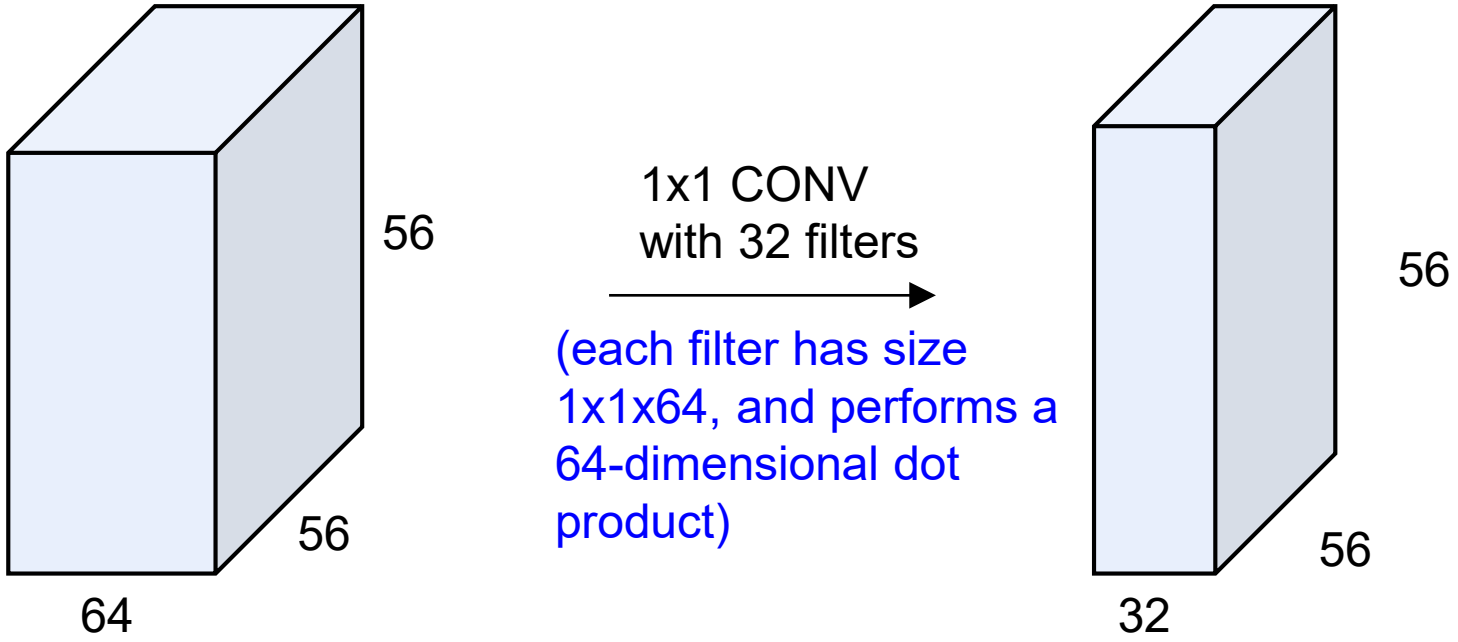
Try Again

Continue

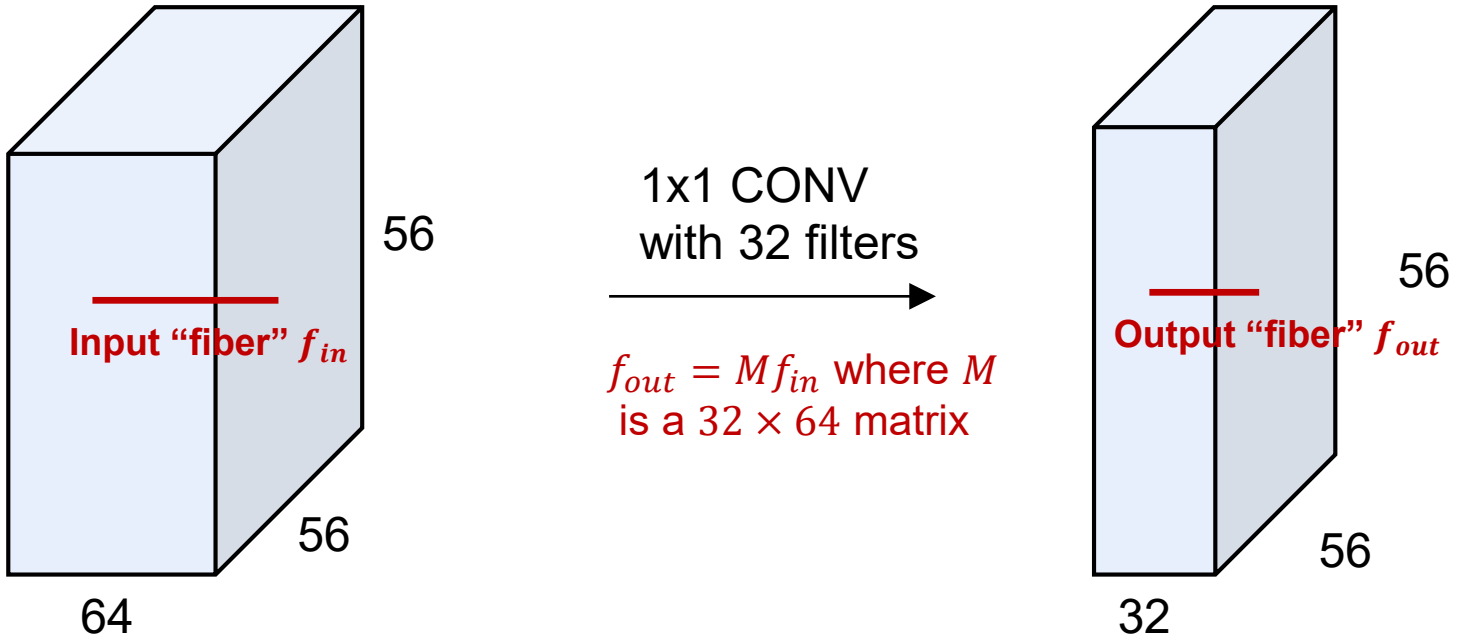
Summary. To summarize, the Conv Layer:

- Accepts a volume of size $W_1 \times H_1 \times D_1$
- Requires four hyperparameters:
  - Number of filters K,
  - their spatial extent F,
  - the stride S,
  - the amount of zero padding P.
- Produces a volume of size $W_2 \times H_2 \times D_2$ where:
  - $W_2 = (W_1 - F + 2P)/S + 1$
  - $H_2 = (H_1 - F + 2P)/S + 1$ (i.e. width and height are computed equally by symmetry)
  - $D_2 = K$
- With parameter sharing, it introduces $F \cdot F \cdot D_1$ weights per filter, for a total of $(F \cdot F \cdot D_1) \cdot K$ weights and K biases.
- In the output volume, the d-th depth slice (of size $W_2 \times H_2$) is the result of performing a valid convolution of the d-th filter over the input volume with a stride of S, and then offset by d-th bias.

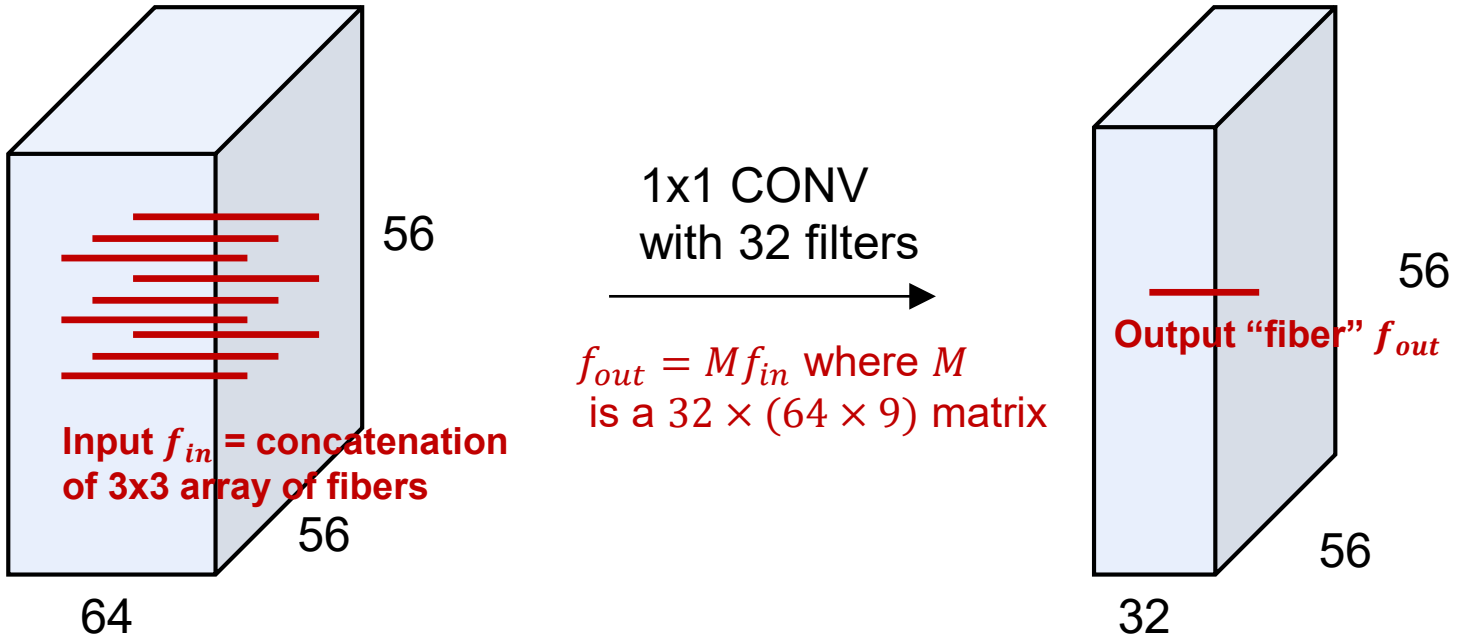
(btw, 1x1 convolution layers make perfect sense)



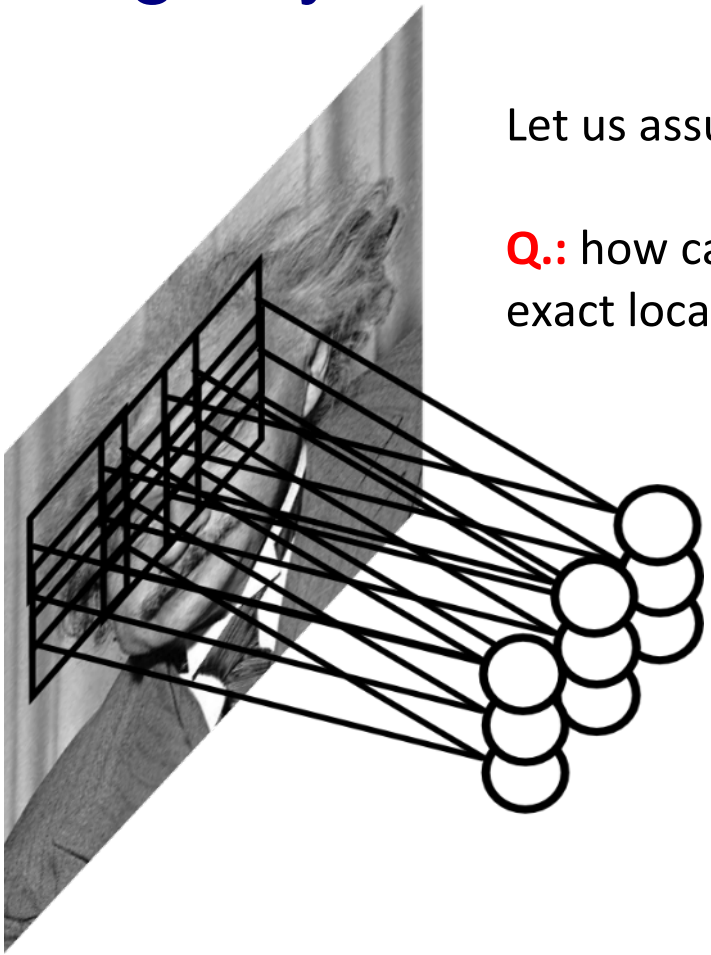
(btw, 1x1 convolution layers make perfect sense)



Aside: convolution via matrix multiply: im2col



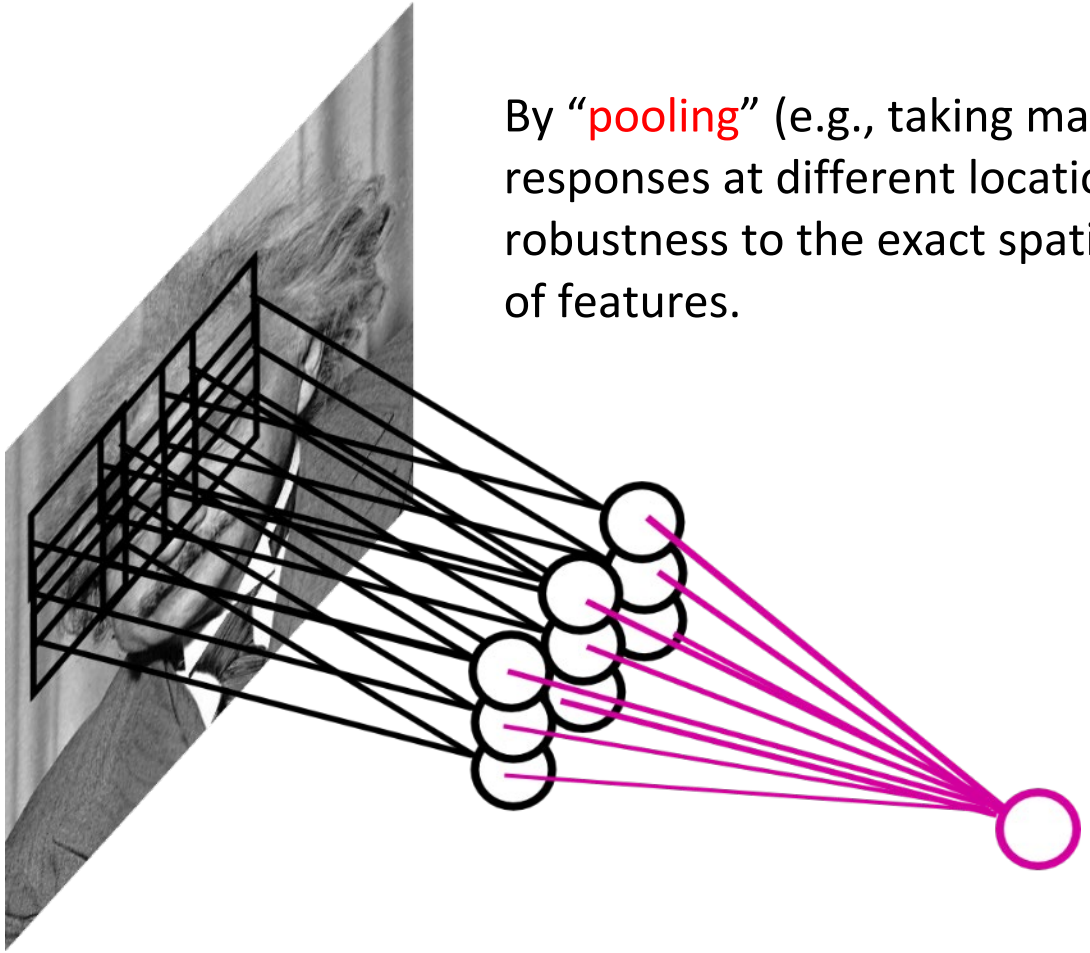
Pooling Layer



Let us assume filter is an “eye” detector.

Q.: how can we make the detection robust to the exact location of the eye?

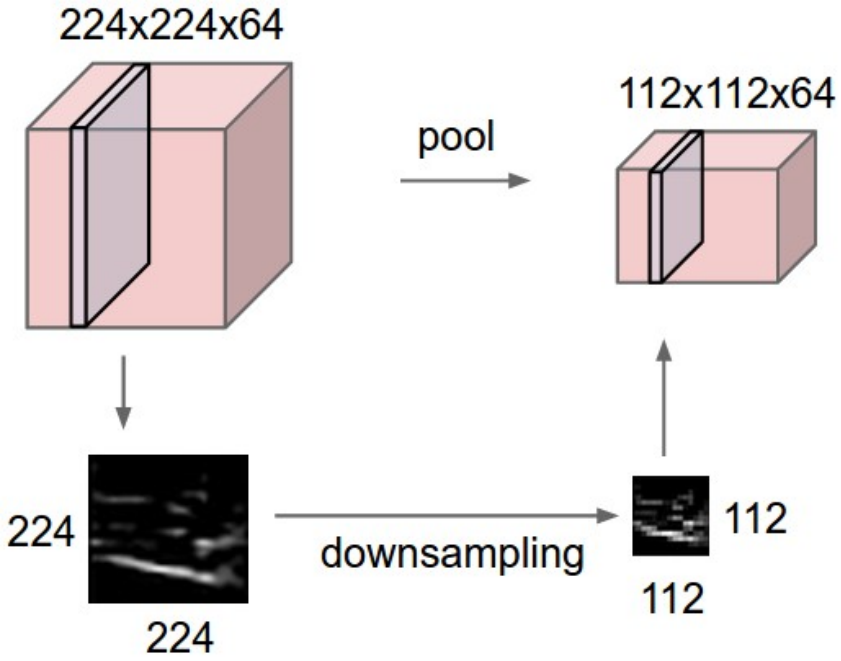
Pooling Layer



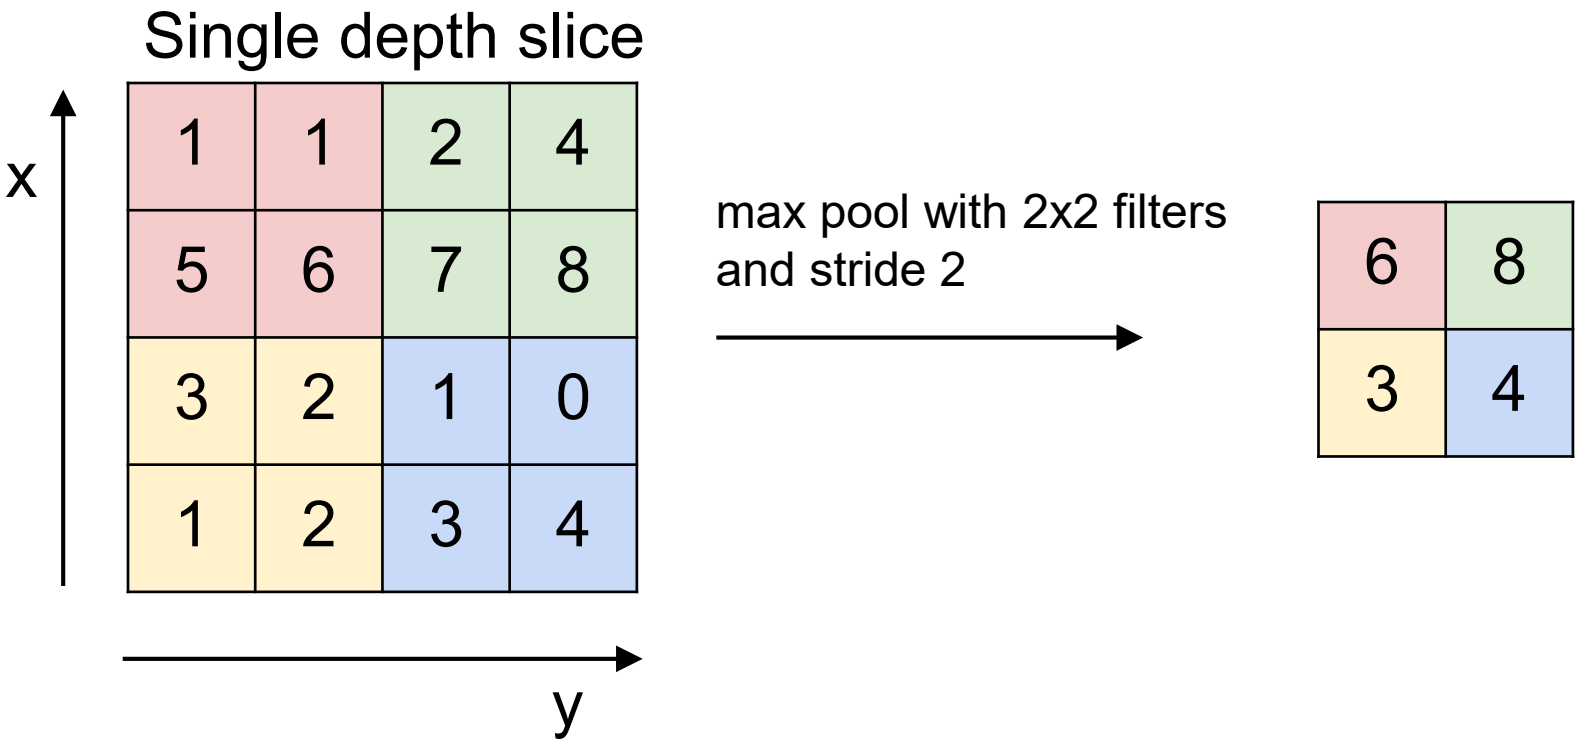
By “pooling” (e.g., taking max) filter responses at different locations we gain robustness to the exact spatial location of features.

Pooling layer

- makes the representations smaller and more manageable
- operates over each activation map independently:



MAX POOLING



Single depth slice
x
y
1 1 2 4
5 6 7 8
3 2 1 0
1 2 3 4
max pool with 2x2 filters
and stride 2
6 8
3 4

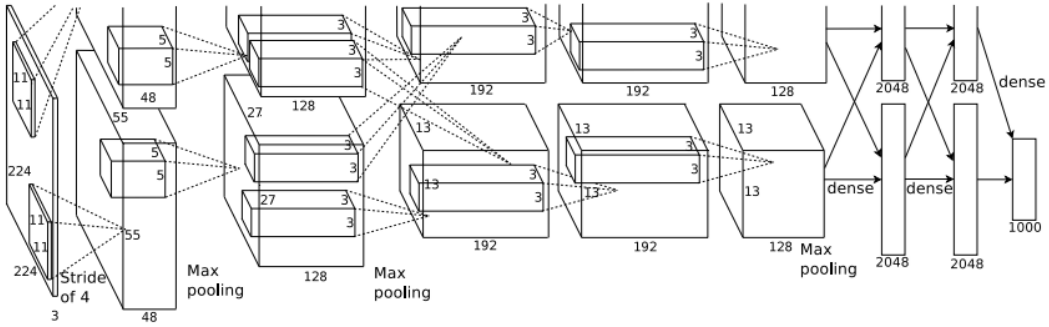
Case Study: AlexNet

[Krizhevsky et al. 2012]



Input: 227x227x3 images

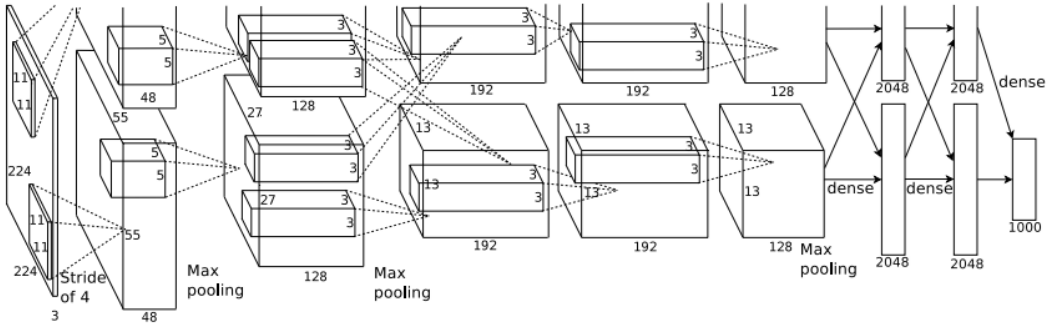
First layer (CONV1): 96 11x11 filters applied at stride 4

=>

Q: what is the output volume size? Hint: (227-11)/4+1 = 55

Case Study: AlexNet

[Krizhevsky et al. 2012]



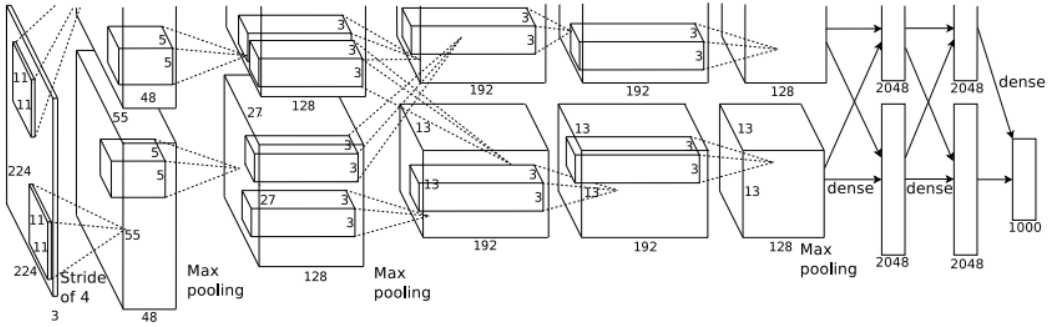
Input: 227x227x3 images

First layer (CONV1): 96 11x11 filters applied at stride 4
=>
Output volume **[55x55x96]**

Q: What is the total number of parameters in this layer?

Case Study: AlexNet

[Krizhevsky et al. 2012]

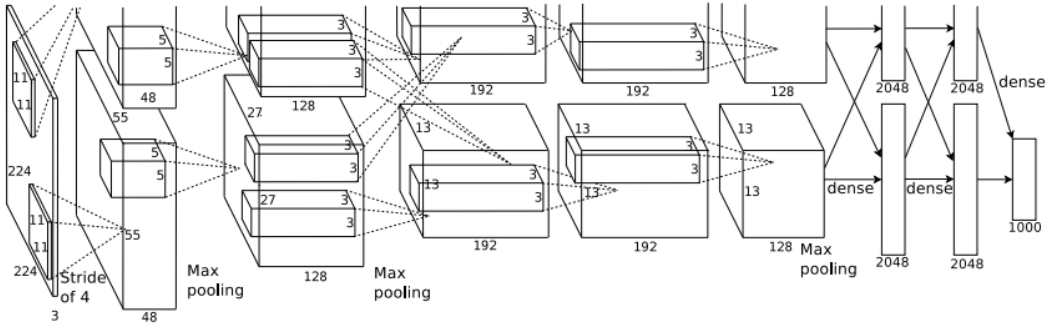


Input: 227x227x3 images

First layer (CONV1): 96 11x11 filters applied at stride 4
=>
Output volume **[55x55x96]**
Parameters: (11*11*3+1)*96 = **35K**

Case Study: AlexNet

[Krizhevsky et al. 2012]

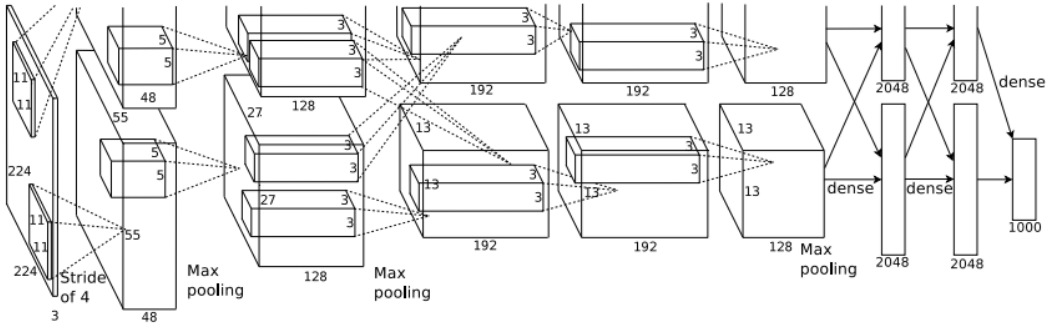


Input: 227x227x3 images
After CONV1: 55x55x96

Second layer (POOL1): 3x3 filters applied at stride 2

Q: what is the output volume size? Hint: (55-3)/2+1 = 27

Case Study: AlexNet



Input: 227x227x3 images
After CONV1: 55x55x96

Second layer (POOL1): 3x3 filters applied at stride 2
Output volume: 27x27x96
Q: what is the number of parameters in this layer?

A. (2x2x96)*96 = 36864

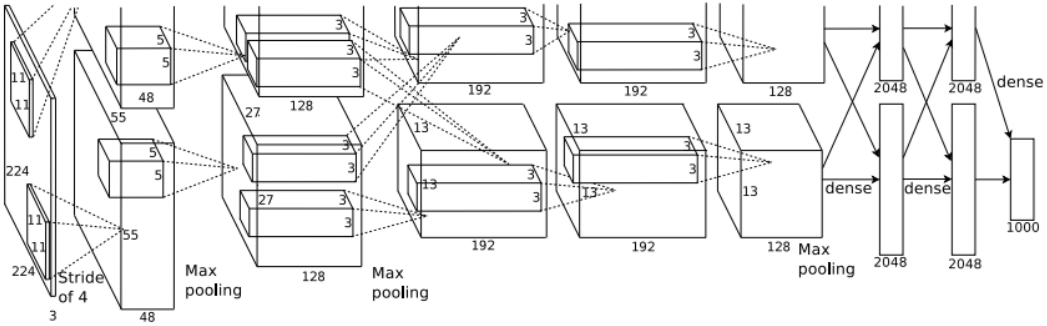
B. (2x2x96+1)*96 = 36960

C. (2x2x96+1) = 385

D. 0

Oops!

Input: 227x227x3 images
After CONV1: 55x55x96



Second layer (POOL1): 3x3 filters applied at stride 2
Output volume: 27x27x96
A Pooling Layer has no parameters!

A. ~~(2x2x96)*96 = 36864~~

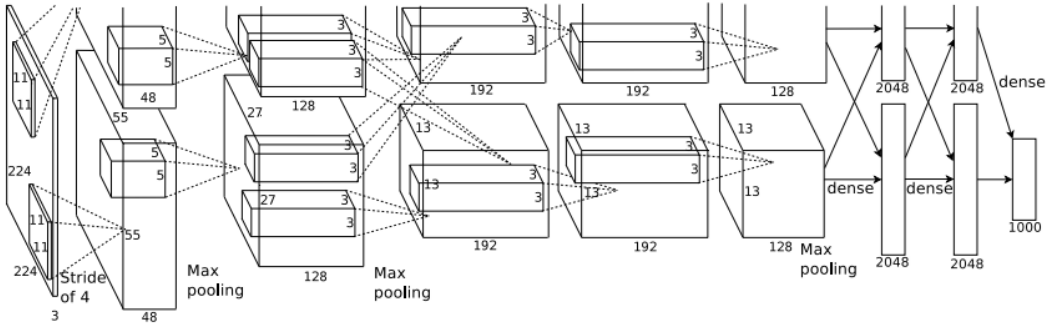
B. ~~(2x2x96+1)*96 = 36960~~

C. ~~(2x2x96+1) = 385~~

Try Again

Continue

Yes!



Input: 227x227x3 images
After CONV1: 55x55x96

Second layer (POOL1): 3x3 filters applied at stride 2
Output volume: 27x27x96
A pooling layer has no parameters! Its just a windowed max operation.

D. 0

Details/Retrospectives:
- first use of ReLU
- used LRNorm layers (not common anymore)
- heavy data augmentation
- dropout 0.5
- batch size 128
- SGD Momentum 0.9
- Learning rate 1e-2, reduced by 10 manually when val accuracy plateaus
- L2 weight decay 5e-4
- 7 CNN ensemble: 18.2% -> 15.4%

“You need a lot of a data if you want to train/use CNNs”

Transfer Learning with CNNs

1. Train on Imagenet

Transfer Learning with CNNs

1. Train on Imagenet

2. If small dataset: fix all weights (treat CNN as fixed feature extractor), retrain only the classifier

i.e. swap the Softmax layer at the end

Transfer Learning with CNNs

1. Train on Imagenet

2. If small dataset: fix all weights (treat CNN as fixed feature extractor), retrain only the classifier

i.e. swap the Softmax layer at the end

3. If you have medium sized dataset, **"finetune"** instead: use the old weights as initialization, train the full network or only some of the higher layers

retrain bigger portion of the network, or even all of it.

Transfer Learning with CNNs

1. Train on Imagenet

2. If small dataset: fix all weights (treat CNN as fixed feature extractor), retrain only the classifier

i.e. swap the Softmax layer at the end

3. If you have medium sized dataset, **"finetune"** instead: use the old weights as initialization, train the full network or only some of the higher layers

retrain bigger portion of the network, or even all of it.

tip: use only ~1/10th of the original learning rate in finetuning to player, and ~1/100th on intermediate layers

Case Study: VGGNet

[Simonyan and Zisserman, 2014]

Only 3x3 CONV stride 1, pad 1
and 2x2 MAX POOL stride 2

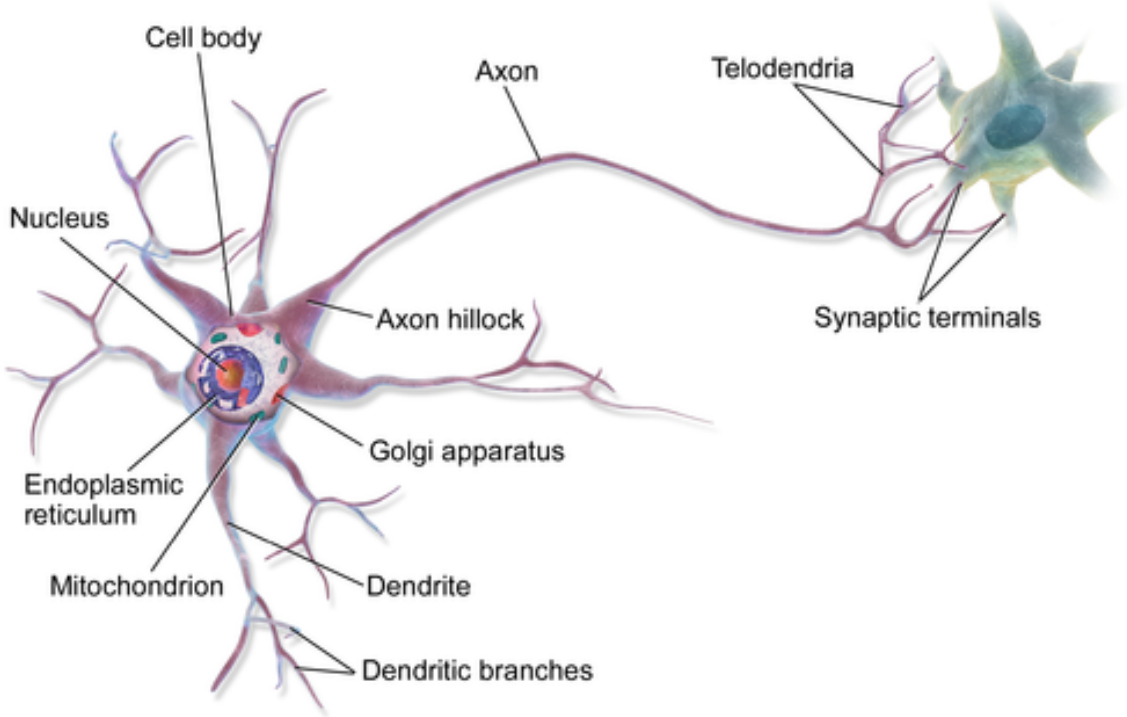
Summary

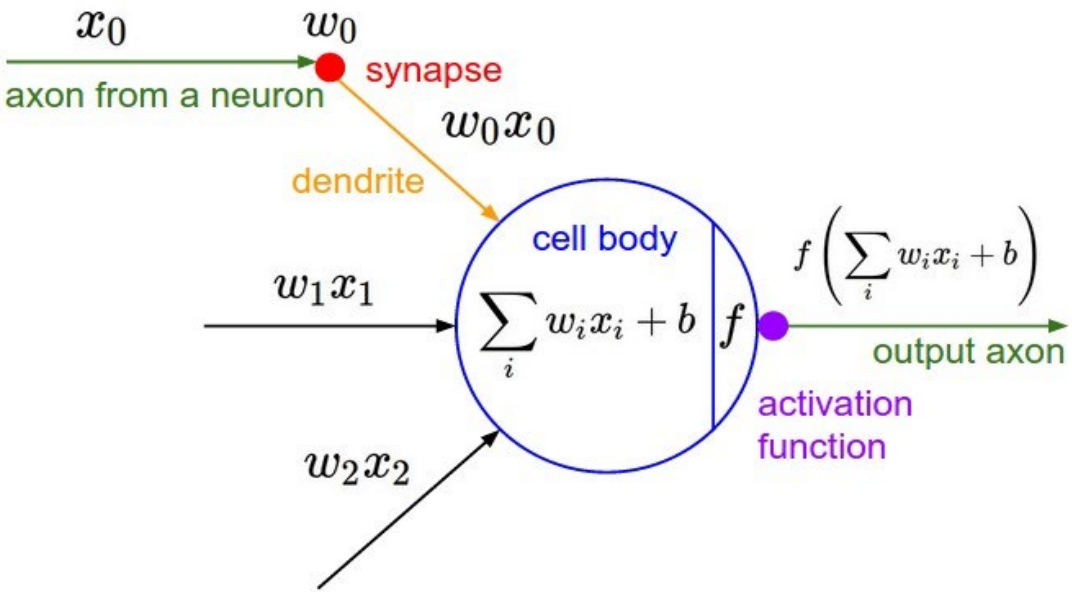
- ConvNets stack CONV,ReLU,POOL,FC layers
- Trend towards smaller filters and deeper architectures
- Trend towards getting rid of POOL/FC layers (just CONV)
- Early architectures look like

  [(CONV-RELU)*N-POOL?]*M-(FC-RELU)*K,SOFTMAX
- but recent advances such as ResNet/GoogLeNet use only Conv-ReLU, 1x1 convolutions, global max pooling and Softmax

Activation Functions: Biological Inspiration



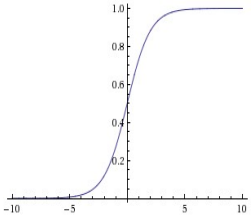
Activation Functions



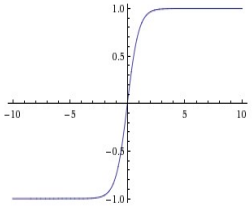
Activation Functions

Sigmoid

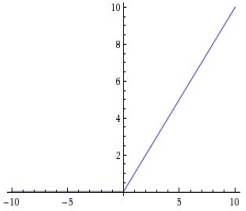
$$\sigma(x) = 1/(1+e^{-x})$$



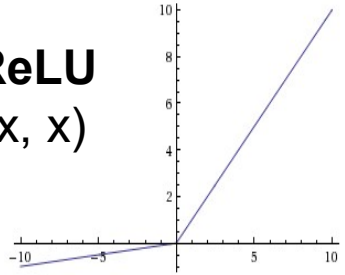
tanh tanh(x)



ReLU max(0,x)



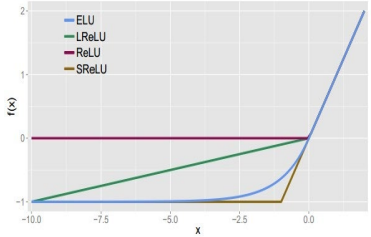
Leaky ReLU
max(0.1x, x)



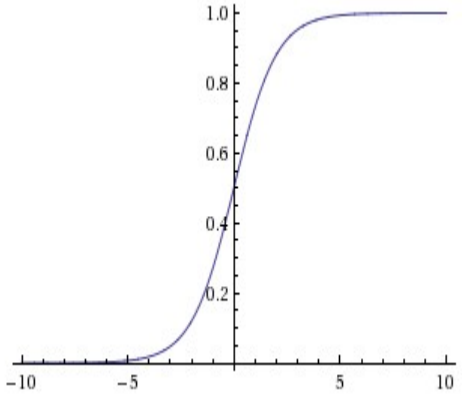
Maxout $\max(w_1^T x + b_1, w_2^T x + b_2)$

ELU

$$f(x) = \begin{cases} x & \text{if } x > 0 \\ \alpha\,(\exp(x) - 1) & \text{if } x \le 0 \end{cases}$$



Activation Functions

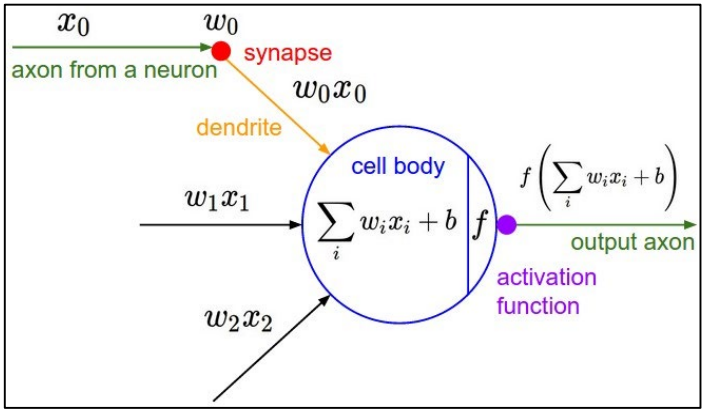


Sigmoid (logistic function)

$$\sigma(x) = 1/(1 + e^{-x})$$

- Squashes numbers to range [0,1] – can kill gradients.
- A key element in LSTM networks – “control signals”
- Good for learning “logical” functions, – good for non-linear control (robots)
- Not as good for image networks (replaced by RELU)
- Not zero-centered

Consider what happens when the input to a neuron (x) is always positive:

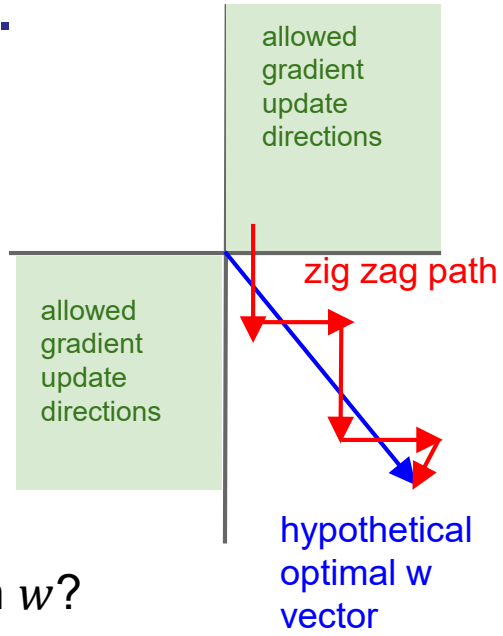


$$f\left(\sum_i w_i x_i + b\right)$$

What can we say about the gradients on w?

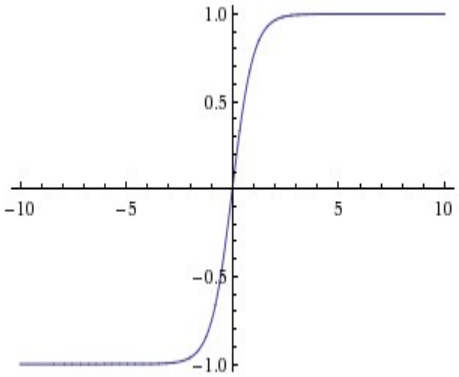
Consider what happens when the input to a neuron is always positive...

$$f\left(\sum_i w_i x_i + b\right)$$



What can we say about the gradients on w?
Always all positive or all negative :(
(this is also why you want zero-mean data!)

Activation Functions

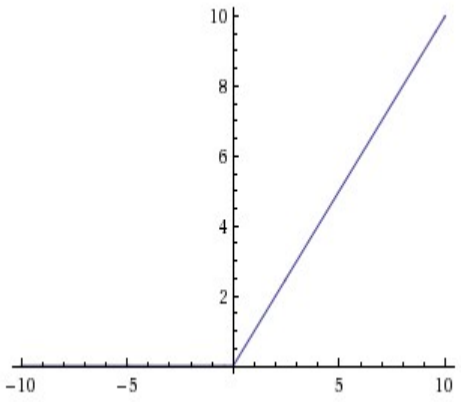


tanh(x)

- Squashes numbers to range [-1,1]
- Zero centered (nice)
- Still kills gradients when saturated :(
- Also used in LSTMs for bounded, signed values.
- Not as good for binary functions

[LeCun et al., 1991]

Activation Functions

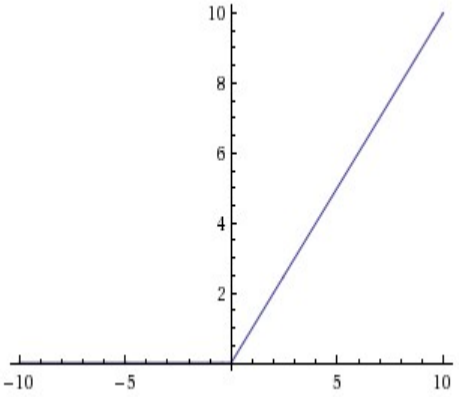


ReLU
(Rectified Linear Unit)

- Computes $f(x) = \max(0, x)$
- Does not saturate (in +region)
- Converges faster than sigmoid/tanh on image data (e.g. 6x)
- Not suitable for logical functions
- Not for control in recurrent nets

[Krizhevsky et al., 2012]

Activation Functions

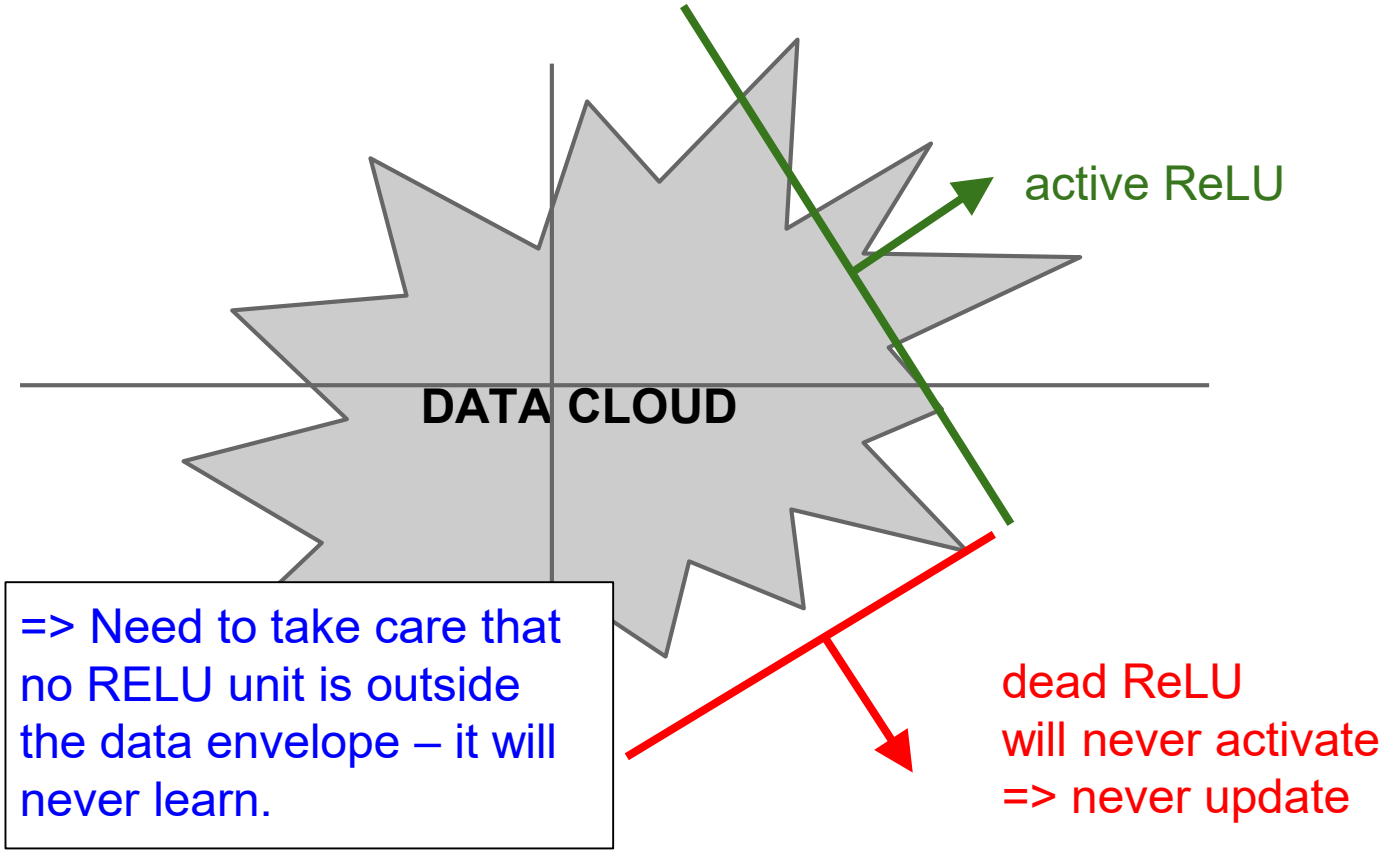


ReLU
(Rectified Linear Unit)

- Computes $f(x) = \max(0, x)$
- Does not saturate (in +region)
- Very computationally efficient
- Converges much faster than sigmoid/tanh in practice (e.g. 6x)

- Not zero-centered output
- An annoyance:

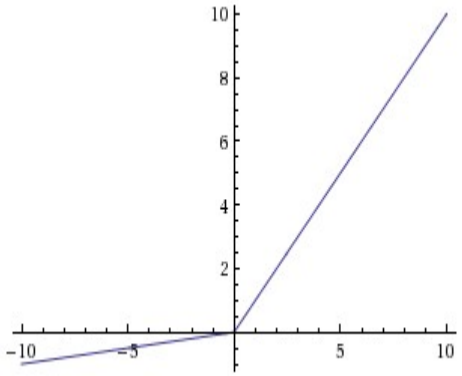
hint: what is the gradient when x < 0?



active ReLU
DATA CLOUD
=> Need to take care that no RELU unit is outside the data envelope – it will never learn.
dead ReLU
will never activate
=> never update

Activation Functions

[Mass et al., 2013]
[He et al., 2015]



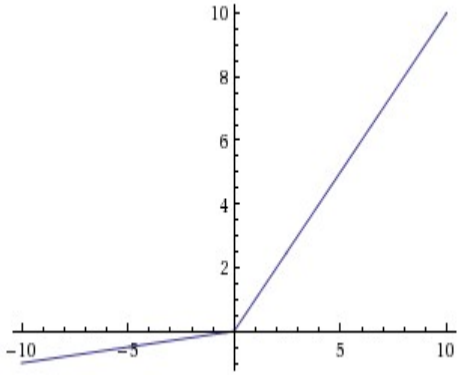
- Does not saturate
- Converges faster than sigmoid/tanh on image data(e.g. 6x)
- **will not “die”.**

Leaky ReLU

$$f(x) = \max(0.01x, x)$$

Activation Functions

[Mass et al., 2013]
[He et al., 2015]



- Does not saturate
- Converges faster than sigmoid/tanh on image data (e.g. 6x)
- **will not "die".**

Leaky ReLU

$$f(x) = \max(0.01x, x)$$

Parametric Rectifier (PReLU)

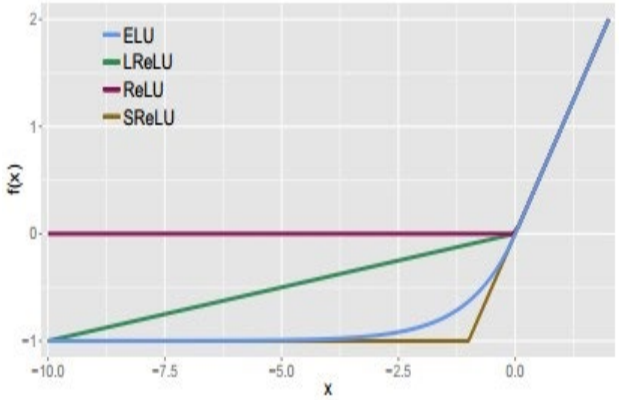
$$f(x) = \max(\alpha x, x)$$

backprop into α (parameter)

Activation Functions

[Clevert et al., 2015]

Exponential Linear Units (ELU)



- All benefits of ReLU
- Does not die
- Closer to zero mean outputs

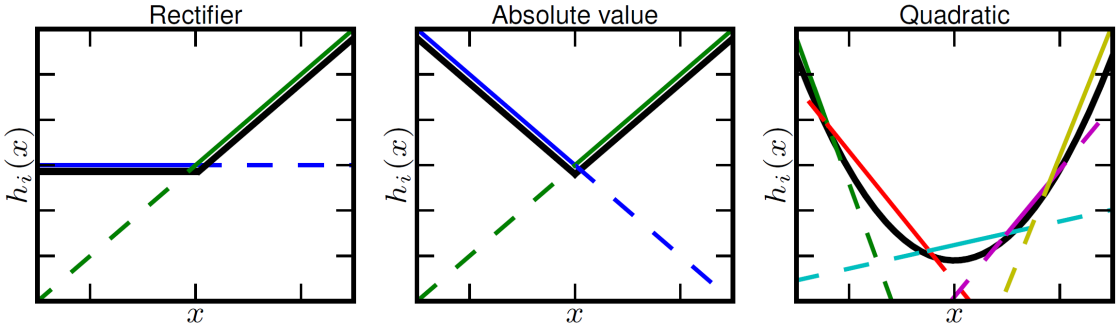
$$f(x) = \begin{cases} x & \text{if } x > 0 \\ \alpha\left(\exp(x) - 1\right) & \text{if } x \leq 0 \end{cases}$$

Maxout “Neuron”

[Goodfellow et al., 2013]

- Does not have the basic form of dot product -> nonlinearity
- Generalizes ReLU and Leaky ReLU
- Linear Regime! Does not saturate! Does not die!

$\max(w_1^T x + b_1, w_2^T x + b_2)$ can learn:



Problem: doubles the number of parameters/neuron :(

TLDR: In practice:

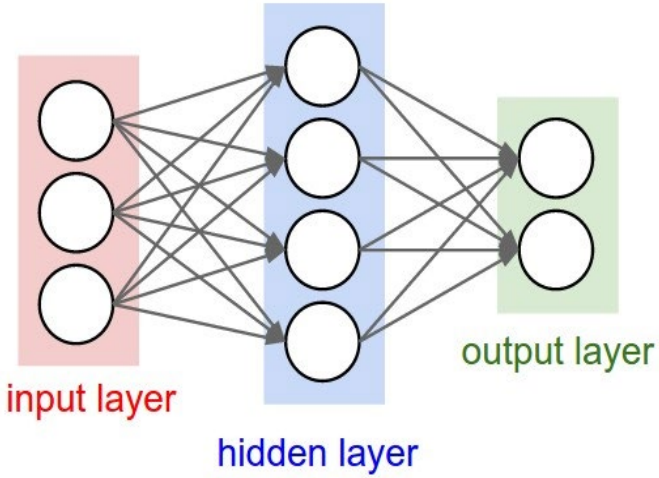
Try everything. Usually:

- Use ReLU on early image layers.
- Try out Leaky ReLU / Maxout / ELU.
- Use sigmoids for smooth functions, e.g. robot control.
- Sigmoids are also good for logical functions AND/OR.

Weight Initialization

Weight Initialization

- Q: what happens when W=0 init is used?



Weight Initialization

First idea: **Fixed random initialization**

e.g. gaussian with zero mean and fixed variance

$$W_{ij} \sim \mathcal{N}(0, 0.0001)$$

Works OK for small networks. Used in Alexnet.

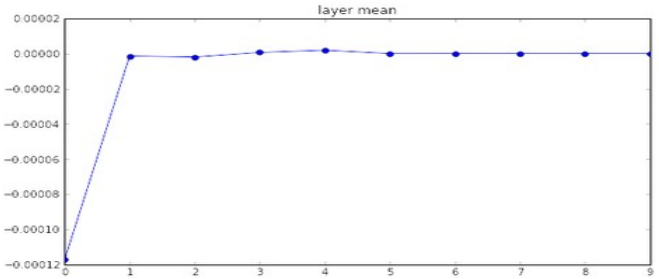
Problem is that activations are scaled by weights in the forward pass.

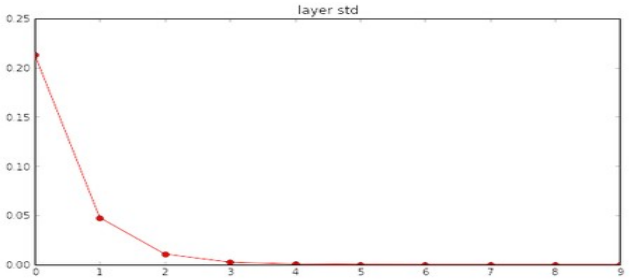
If the initial weights are too small/large, the activations will vanish or explode during the forward pass.

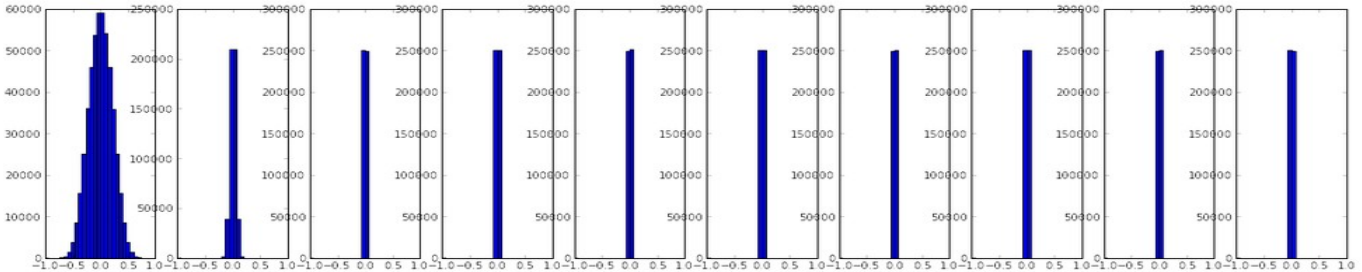
The gradients will do the same in the backward pass…

Activations with Random Weight init

```
input layer had mean 0.000927 and std 0.998388
hidden layer 1 had mean -0.000117 and std 0.213081
hidden layer 2 had mean -0.000001 and std 0.047551
hidden layer 3 had mean -0.000002 and std 0.010630
hidden layer 4 had mean 0.000001 and std 0.002378
hidden layer 5 had mean 0.000002 and std 0.000532
hidden layer 6 had mean -0.000000 and std 0.000119
hidden layer 7 had mean 0.000000 and std 0.000026
hidden layer 8 had mean -0.000000 and std 0.000006
hidden layer 9 had mean 0.000000 and std 0.000001
hidden layer 10 had mean -0.000000 and std 0.000000
```







Analysis of activation growth

Consider a linear layer (affine or convolutional), and define the **fan-in F** as the number of input neurons that contribute to each output.

- For an affine layer, the fan-in is just the number of neurons in the input layer.
- For a convolutional layer, the fan-in is $F_H \times F_W \times C$ where C is the depth of the input layer.

Then each output activation

$$a_{out} = \sum_{i=1}^{F} W_i a\_i$$

and assuming the activations and weights are independent, same variance:

$$\mathrm{Var}(a_{out}) = F\,\mathrm{Var}(W)\,\mathrm{Var}(a_{in})$$

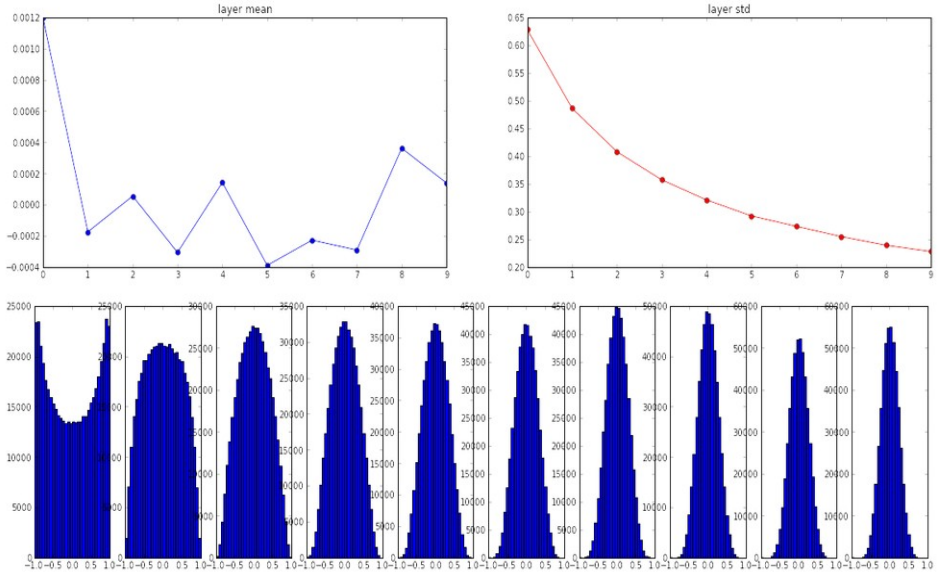
To get the same variance on input and output, we want $\mathbf{Var}(\boldsymbol{W}) = \mathbf{1}/\boldsymbol{F}$

Xavier Initialization

```
input layer had mean 0.001800 and std 1.001311
hidden layer 1 had mean 0.001198 and std 0.627953
hidden layer 2 had mean -0.000175 and std 0.486051
hidden layer 3 had mean 0.000055 and std 0.407723
hidden layer 4 had mean -0.000306 and std 0.357108
hidden layer 5 had mean 0.000142 and std 0.320917
hidden layer 6 had mean -0.000389 and std 0.292116
hidden layer 7 had mean -0.000228 and std 0.273387
hidden layer 8 had mean -0.000291 and std 0.254935
hidden layer 9 had mean 0.000361 and std 0.239266
hidden layer 10 had mean 0.000139 and std 0.228008
```

```
W = np.random.randn(fan_in, fan_out) / np.sqrt(fan_in) # layer initialization
```

"Xavier initialization" [Glorot et al., 2010]

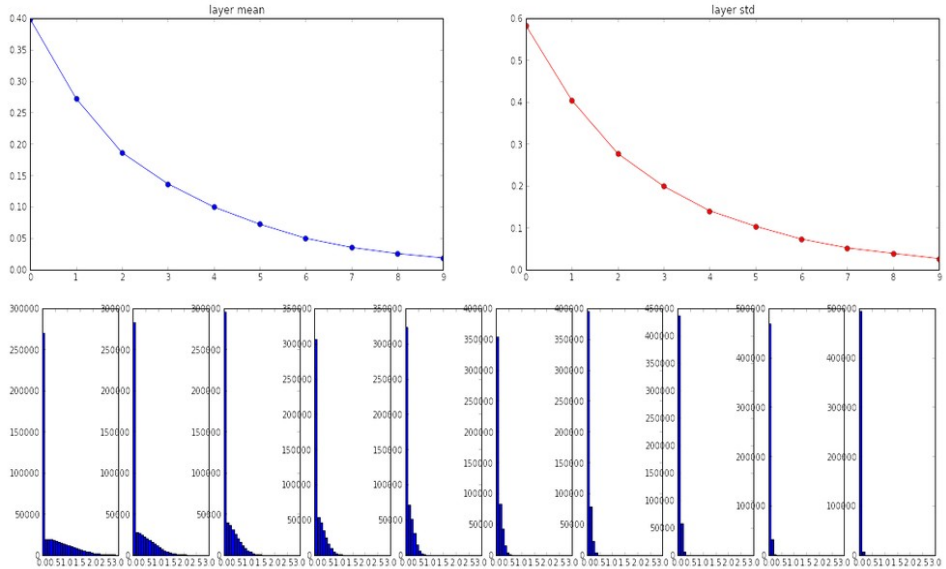


Accounting for ReLUs

```
input layer had mean 0.000501 and std 0.999444
hidden layer 1 had mean 0.398623 and std 0.582273
hidden layer 2 had mean 0.272352 and std 0.403795
hidden layer 3 had mean 0.186076 and std 0.276912
hidden layer 4 had mean 0.136442 and std 0.198685
hidden layer 5 had mean 0.099568 and std 0.140299
hidden layer 6 had mean 0.072234 and std 0.103280
hidden layer 7 had mean 0.049775 and std 0.072748
hidden layer 8 had mean 0.035138 and std 0.051572
hidden layer 9 had mean 0.025404 and std 0.038583
hidden layer 10 had mean 0.018408 and std 0.026076
```

```
W = np.random.randn(fan_in, fan_out) / np.sqrt(fan_in) # layer initialization
```

Our analysis assumed that layers were linear.
Not accurate with ReLU layers.

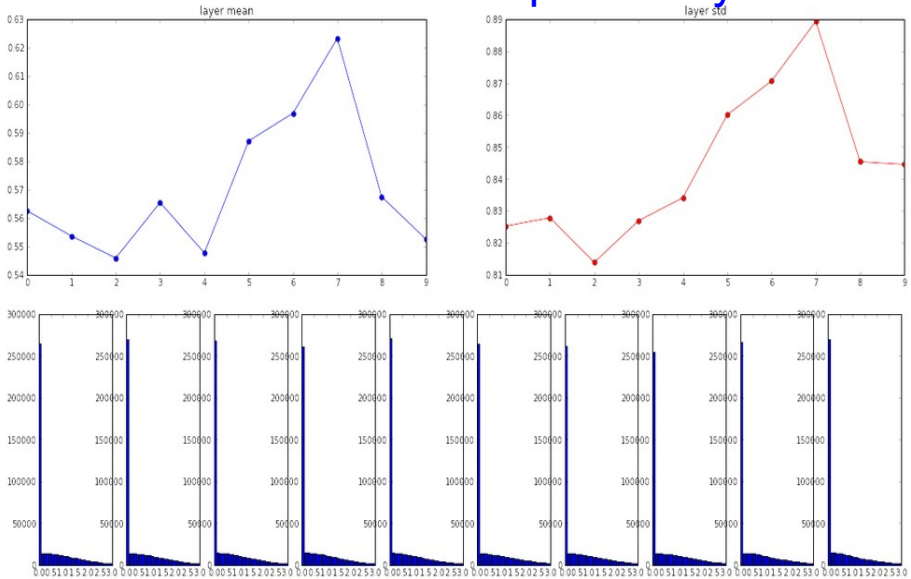


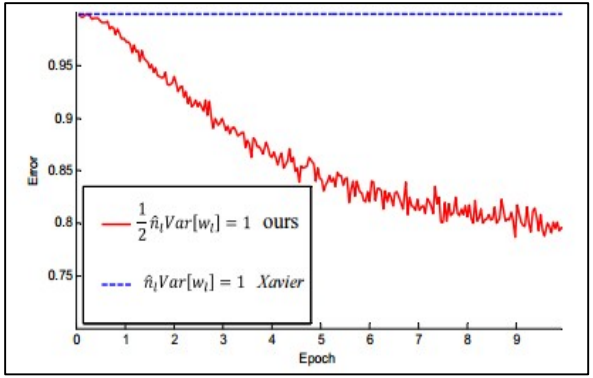
ReLU adjustment to Xavier

```
input layer had mean 0.000501 and std 0.999444
hidden layer 1 had mean 0.562488 and std 0.825232
hidden layer 2 had mean 0.553614 and std 0.827835
hidden layer 3 had mean 0.545867 and std 0.813855
hidden layer 4 had mean 0.565396 and std 0.826902
hidden layer 5 had mean 0.547678 and std 0.834092
hidden layer 6 had mean 0.587103 and std 0.860035
hidden layer 7 had mean 0.596867 and std 0.870610
hidden layer 8 had mean 0.623214 and std 0.889348
hidden layer 9 had mean 0.567498 and std 0.845357
hidden layer 10 had mean 0.552531 and std 0.844523
```

```
W = np.random.randn(fan_in, fan_out) / np.sqrt(fan_in/2) # layer initialization
```

He et al., 2015 (note additional /2)
factor of 2 doesn't seem like much, but it applies multiplicatively 150 times in a large ResNet.





Proper initialization remains important…

We will find later (Transformer Networks) that weight initialization is essential for converging to the best model.
